GEOLOGIC HAZARDS

As an engineer, you should be aware of the existence of geologic hazards and their potential impact on engineering projects. Geologic hazards are geologic phenomena that present common risks to life or property. Geologic hazards are usually identified during site exploration and investigation. The purpose of the lectures on natural hazards is to familiarize you with both the causes and effects of such occurrences and alert you to proper scientific solutions and land-use management practices that can alleviate or eliminate disastrous consequences.

Natural geologic hazards can be divided into two groups. First, those associated with particular earth materials. Examples include swelling soils and rocks, toxic minerals (asbestos, acid drainage) and toxic gases (radon gas). The second group includes hazards associated with earth processes (earthquakes, volcanoes, landslides, avalanches, rock slides and rock falls, soil creep, subsidence, floods, frost heave, coastal hazards).

Natural hazards are complemented with man-made hazards such as water pollution, mine subsidence, rock bursts, pumping, waste disposal, carbon emission, global warming, and ozone depletion. Understanding these hazards requires a multidisciplinary approach. These issues are interdisciplinary with biology, engineering, chemistry, and environmental sciences.

Geologic hazards are not predictable and often result in loss of life, property losses and indirect losses (e.g. business disruption). Geologic hazards are not trivial or forgiving; in terms of loss of life, geologic hazards compare with the most severe catastrophes of this century (see Tables 1 and 2). Precise figures are difficult to compute, but the monetary and human loss due to such hazards is staggering. Natural disasters annually wrench more than $40 billion from the global economy and take an average of 200,000 human lives. The Federal Emergency Management agency (FEMA) estimates the nation’s annual earthquake property damage losses at about $4.4 billion. This compares to annual flood losses of $5.2 billion between 1989 and 1998 according to National Weather Service data. The National Climatic Data Center estimates $5.4 billion in annual hurricane losses for that period. The United States has been losing of the order of $1 billion per week to natural disasters in recent years. Since 1989, the United States has suffered more than $90 billion in insured losses from natural disasters.

With growing urbanization and more extensive land use, the threat of loss of life and property from geologic occurrences has increased. For example, the 1906 San Francisco earthquake, with a magnitude of 8.3 on the Richter scale, caused an estimated $350 million to $1 billion in damage and took about 500 lives. According to the U.S.’s Insurance Information Institute, if an earthquake with an 8.3 magnitude were to hit San Francisco, as it did in 1906, losses could reach $225 billion.

In response to the rapid escalating toll of human and economic losses from natural disasters, the United Nations (UN) General Assembly proclaimed the decade of 1990 – 2000, in its resolution 44/236 of 1989, as the International Decade for Natural Disaster Reduction (IDNDR). The resolution made clear a statement of its objectives:
Table 1. Casualties from specific geologic hazards compared with familiar societal catastrophes (from The Citizen's Guide to Geologic Hazards, 1993.)

(data on familiar societal catastrophes from The World Almanac, 1993, New York, Pharos Books; and The Universal Almanac, 1993, Kansas City, Andrews and McMeel; geological catastrophes compiled from Tufty, 1969, and Office of Foreign Disaster Assistance, 1992, Disaster History.)

“The objective of the Decade is to reduce through concerted international action, especially in the developing countries, the loss of life, property damage, and social and economic disruption caused by natural disasters, such as earthquakes, wind storms, tsunamis, floods, landslides, volcanic eruptions, wildfires, grasshopper and locust infestations, drought and desertification and other calamities of natural origin.”

The targets set by the UN General Assembly for the decade were that, by the year 2000, all countries, as part of their plan to achieve sustainable development, should have the following in place: (1) comprehensive national assessments of risk of natural hazards, with these assessments taken into account in development plans, (2) mitigation plans at the national level and or local levels involving long-term prevention awareness, and (3) ready access to global, regional, national, and local warning systems and broad dissemination of warnings.

Ironically, losses due natural hazards have not declined between 1990 and 2000; they have risen dramatically. Hurricane Andrew ($27 billion), the Midwest floods of 1993 ($21 billion), and the Northridge earthquake of 1994 ($45 billion) each inflicted losses of tens of billions of dollars.

How can we cope with geologic hazards? There are four options:

1. Avoid the areas where known hazards exist. Such areas can be converted into parks, for instance.
Table 2. Economic costs of geologic hazards in the U.S. (from *The Citizen's Guide to Geologic Hazards*, 1993.)

(2) Evaluate the potential risk of a hazard, if activated.
(3) Minimize the effect of the hazards by engineering design and appropriate zoning.
(4) Develop a network of insurance and contingency plans to cover potential loss or damage from hazards.

**Homework Assignment # 7** (Due Wednesday February 18, 2009)

1) Find an estimate of the losses associated with recent geo-hazards between 2000 and now.

3) Go to the following web sites:
   - Colorado Geological Survey: [http://geosurvey.state.co.us](http://geosurvey.state.co.us)
   - Boulder County Comprehensive Plan: [www.co.boulder.co.us/lu/bcep](http://www.co.boulder.co.us/lu/bcep)
   - Geology of the Boulder area: [http://bcn.boulder.co.us/basin/watershed/geology](http://bcn.boulder.co.us/basin/watershed/geology)
   - Geologic History of Boulder area: [http://bcn.boulder.co.us/basin/natural/geology/historic.html](http://bcn.boulder.co.us/basin/natural/geology/historic.html)
   - Map of Geologic Hazards for Boulder County: [www.co.boulder.co.us/lu/bcep/images/ghca.jpg](http://www.co.boulder.co.us/lu/bcep/images/ghca.jpg)
   - Read the article “Geology of Boulder, USA” by S. Bilodeau et al. (1987). Two copies of the article have been placed outside ECOT 546 with a sign-up sheet.

Answer the following questions:

- What is the difference between a geologic hazard and a geologic constraint?
- What are the major geologic hazards and constraints in Boulder City and Boulder County?
- Where should one go to get more information about the extent and importance of those hazards and constraints (city offices, county offices, etc.)?

This is a group project.
